

## Simple example for text-decoration

The "text-decoration"-property describes decorations that are added to the text of an element. If the property is specified for a block-level element, it should affect all inline-level descendants of the element. If it is specified for (or affects) an inline-level element, it affects all boxes generated by the element.

Example: underline

```
<fo:inline text-decoration="underline">underline</fo:inline>
```

This is simple test of the text-decoration 'underline'.

This is simple test with a bigger font-size.

This is simple test with a monospaced font.

The following text decorations are defined in the REC:

- none
- underline
- overline
- ~~line-through~~
- blink
- no-underline
- no-overline
- no-line-through
- no-blink

And now more than a word...

This is a whole block wrapped in fo:inline with the property text-decoration="underline". Some more Text to get at least two lines.

This is simple test with a bigger font-size.

This is simple test with a ~~monospaced font~~.

What about underlining of whitespace only ?

A whole block should work now. And again some more text to get at least two lines.

Let's see if all inline-areas are affected ...

This is a workaround for the combination of ~~different text-decoration~~

values...

Enter your name here: \_\_\_\_\_

The following blocks demonstrate the letter-spacing attribute:

This block does not use any letter-spacing.

This block uses a letter-spacing of 1mm.

This block uses an fo:inline element to demonstrate letter-spacing.
